

# Data Quality & Forensics Report

## CredResolve — Data Analyst Assignment

| Issue              | Evidence                                                                                  | Treatment / decision                                                                                        | Impact                                                                      |
|--------------------|-------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------|
| Duplicate payments | 972 duplicate payment rows.                                                               | Deduplicate on the full payment-event key; do not deduplicate on payment_reference alone.                   | Raw successful recovery is inflated by ■2.50 Cr (1.86%).                    |
| Duplicate calls    | 1,350 duplicate call_id rows; 11 IDs have conflicting timestamps.                         | Keep one deterministic row per call_id and flag conflicting records for review.                             | Prevents call-volume and contact-rate inflation.                            |
| Campaign windows   | 80.3% of targeting rows fall outside active campaign windows.                             | Exclude invalid-window targeting records from campaign attribution.                                         | Campaign/channel attribution is unreliable if these rows are included.      |
| Timezone           | 66.7% of calls disagree with vendor timezone.                                             | Retain raw timezone; canonicalize only after source reconciliation.                                         | Hour/day performance comparisons can be materially distorted.               |
| Borrower master    | 28,151 duplicate borrower rows; 8,518 IDs have conflicting profile fields.                | Use accounts.borrower_id as the canonical relationship; treat conflicting profile fields as low-confidence. | Geography/profile segmentation should not be treated as fully reliable.     |
| Agent master       | Multiple master rows exist across the 1,000 agent IDs; 1,000 show conflicting attributes. | Use agent_id as the event key; require an effective-dated identity map for vendor/tenure analysis.          | Agent-level attribution and tenure analysis are unsafe from the raw master. |

## Source-of-truth decisions

- accounts.account\_id is the canonical operational entity.
- Successful recovery = payment\_status = SUCCESS after exact event deduplication.
- Campaign/channel payment attribution uses the latest valid targeting event before payment within seven days; strict attribution covers 4.75% of clean successful recovery, so attribution findings are directional.

## Observation window

Targeting and payment data run through 2026-08-08; calls extend to 2026-08-12. August is partial, so Jan–Jul are the comparable full months.
